✓ 2232. Use of deformable packing blocks in aid
of launching of ships. A. G. Anisimovskiy and
A. H. Lirvin. *Sudostroyit. Izd.*, 22, No. 7; 1;
J. Brit. Naval Res. Assn., 1937, 12, obs. 12327. In
Russian. When preparing a ship for launching the
strength of the hull must be specially reinforced to
enable it to withstand the launching stress. This
is particularly important in ships with the machinery
placed aft, since with this weight distribution the
way-end reactions may be especially high. The
article describes a method of reducing the stresses
by introducing an appreciable amount of deformability
into the sliding ways. This is done by placing
special flat blocks of rubber or similar
material between the packing timbers. To
determine the suitability of the materials, the rate
of deformation of the blocks for various rates of
load increase can be determined by means of a
hydraulic press.

TITLE:

Expansion Diagram of Steel Under Direct Stress (Diagramma rastyazheniya stali pri neposredstvennom nagruzhenii)

PERIODICAL:

Zavodskaya Laboratoriya, 1958, Vol 24, Nr 10, pp 1239-1242 (USSR)

ABSTRACT:

The usual machines are used in expansion tests where the expansion of the samples takes place with variable deformation velocity. These machines (as, for instance, the Garagi press) are in class I of the testing machines. In practice, however, a direct stress is frequent where the external forces increase independently of the deformation of the construction (as in bridges, rails, posts etc.). Machines with a direct stress where the expansion of the samples takes place at a constant rate of increasing stress are termed class II of the testing machines. In the present case a machine was constructed which develops a force of up to 3300 kg, and which can regulate the stress velocity from 0 to 800 kg/sec. This machine makes possible investigations of the effect of direct stress on the mechanical properties of some plastics. A scheme of the machine as well as a description of its operation are given. It is mentioned that resistance tensiometers with a recording instrument on the

Collapsible paddings in shipbuilding and ship repair (Sminayishchiyesya prokladki v
sudostroyenii i sudoremonte) Leningrad, Izd-vo "Sudostroyeniye", 1966. 130 p.
illus., bibliog. 2700 copies printed.

TOPIC TAGS: collapsible padding, shipbuilding engineering, shock absorber

PURPOSE AND COVERAGE: This booklet is intended for engineering and technical staff engaged in the construction and repair of seagoing and river vessels, and in other fields of technology. It can be used by students of higher technical schools and institutes. Utilization of collapsible padding in shipbuilding and shiprepair plants is discussed, and the selection of materials, their mechanical properties, and the design and construction of collapsible paddings are described in detail. There are 52 references, 51 of which are Soviet.

TITLE: A unit for technical bending tests of metals in liquid media

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 9, 1962, 104, abstract 91669
(In collection: "Mashiny i pribory dlya ispytaniya metallov",
Kiyev, AN UkrSSR, 1961, 128 - 131)

TEXT: A description is presented of the design of a unit for bending tests of wire specimens under the effect of surface-active and corrosion media (with possible simultaneous application of the potential) in liquid metals and melts. Results are presented which had been obtained from bending tests of electro-polished "St.45" steel wire specimens, 0.85 mm in diameter. The tests were performed in a 26% H₂SO₄ and 3% NaCl solution in distilled water at different D_c and bending speeds. It was established that with greater D_c the number of bends until the failure of the specimen decreases; the most intensive reduction of the steel ductility occurs at D_c < 2 amp/dm²; the hydrogen brittleness increases with reduced bending speed. It is noted that the unit assures stable results of

AUTHOR: Litvin, A. K.; Starchak, V. G.

TITLE: Distribution of hydrogen in the surface layers of steel during electrolytic saturation

SOURCE: Fiziko-khimicheskaya mekhanika materialov, v. 1, no. 3, 1965, 293-298

TOPIC TAGS: hydrogen distribution, surface layer, electrolytic saturation, hydrogen saturation, surface steel layer, saturation time, layer microhardness

ABSTRACT: The investigation of the process of diffusion and mechanism of penetration of hydrogen into metal during electrolytic saturation as well as the elucidation of certain features of the mechanism of brittle fracture of hydrogen-saturated steel require data on the nature of the qualitative and quantitative changes in the concentration of hydrogen in the specimen in the process of saturation. The hydrogen is known to concentrate chiefly in a thin surface layer of the metal. In this connection, the authors investigated specimens of 20 steel (0.18% C, 0.47% Mn, 0.17% Si) annealed at 860-870°C and saturated with hydrogen in a 26% H₂SO₄ solution with cathode polarization. The hydrogen distribution in layers of the specimen in relation to saturation time (30-540 min) was investigated in a special setup for the anodic dissolution of the specimens, using an electrolyte composition of 150 g

Card 1/3

L 20981-66

ACCESSION NR: AP5019653

NaCl + 25 g KNaC₄H₄O₆ per liter of H₂O, with an anode current density of 50 a/decimeter². The concentration of hydrogen during the second stage of saturation (90-540 min) stabilizes in the 5-15 μm deep layer, monotonically increases in the 15-105 μm deep layers, and again stabilizes in the 105-480 μm deep layers. In the layer between 480 and 700 μm the hydrogen content remains virtually fixed and the same as that of the nonsaturated specimens. The mean unit content of hydrogen throughout the layer from 0 to 480 μm during the second stage also somewhat decreases owing to the hydrogen losses in the 5 μm surface layer. Thus, it was established that the maximum concentration of hydrogen in the 5 μm thick surface layer of metal is achieved at the end of the first stage of saturation (60-51 min), whereupon it decreases somewhat with increasing saturation time; at the same time, however, it increases in some of the deeper layers. The nature of the change in hydrogen concentration in the 5 μm thick surface layer corresponds to the change in the microhardness of this layer, within the limits of experimental conditions. Thus, the curve of variation in the microhardness of ferritic grains at the surface of annealed steel 20 reaches its peak at the end of the first stage of saturation with hydrogen, whereupon it decreases. Orig. art. has: 3 figures.

PHASE I BOOK EXPLOITATION SOV/1284

Litvin, Aleksandr Moiseyevich

Osnovy teploenergetiki (Principles of Heat Engineering) 6th ed.,
rev. and enl. Moscow, Gosenergoizdat, 1958. 287 p. 20,950 copies
printed.

Ed.: Shukher, S.M.; Tech. Ed.: Borunov, N.I.

PURPOSE: This monograph is intended as a textbook in the training
of personnel and semiprofessional workers of electric power
stations (brigade leaders, foremen), and of operators of industrial
power plants. It can also be used in schools which include a
brief course of heat engineering in their programs.

COVERAGE: This book presents the fundamentals of heat-power engi-
neering based on Soviet practices. It includes thermodynamics
and heat transfer problems. Much attention is given to power-
plant equipment and operation, fuel combustion, and feed-water
handling. The operation and economics of power plants are also

Card 1/5

Principles of Heat Engineering

SOV/1284

discussed. This new edition is designed to suit the needs of the reader already familiar with the field. The author adds information on recent developments in Soviet power engineering. S.M. Shukher, Eng., edited the manuscript. There are 124 figures.

ABSTRACT:

The author and Engineer A.I. Raygorodskiy propose a simple portable device with which the water-penetrability of concrete can be determined in a few minutes. The device is based on the principle that there is a correlation between water and air permeability of concrete. A description of the above device and a method of evaluating penetrability of concrete is given. The device was

TOPIC TAGS: zinc compound optic material, crystal phosphor, synthetic material, luminescence, luminescence spectrum

ABSTRACT: This is a continuation of earlier research (Kristallografiya v. 9, no. 6, 943, 1964) on hydrothermal synthesis of sodium zinc silicates. The present article describes six different crystal phosphors synthesized by this method, with different relative compositions of the components ($Na_2O-ZnO-SiO_2-H_2O$) and their crystal structures. To obtain luminescent zinc silicates of sodium, an activator in the form of MnO was introduced in the charge. Five out of the six crystals produced a luminescence in the green region of the spectrum under the influence of ultraviolet light, although the maxima were not the same for all crystals. One of the produced crystals was the previously produced willemite $Zn_2SiO_4(Mn)$ whose luminescent properties are well known. However, the maximum obtained for this crystal was somewhat different from the published data, and this difference is ascribed to the difference in the method of preparing the crystal. Orig. art. h.s.: 6 figures.

Title : To The Question of Diffusion Study by the Method of
Radioactive Isotopes.

Orig Pub : Problemy metalloved. i fiz. metallov, sb. 4, 1955, 486-
493.

Abstract : A variant of the absorption method of radiometric analy-
sis was developed. At the measurement of the sample acti-
vity before and after the diffusion annealing, the ratio
of the intensities of β - and γ - components of radiation
in case of mixed radiators, or the ratio of the intensi-
ties of two β spectrum parts in case of pure β - radiators
is determined by this method. The solution of the diffu-
sion equations is modified in order to apply them to
this method. The relative error of the determination of
the diffusion factor is 25%. The experiments were succes-
sful

- 64 -

USSR/Crystals.

B-5

Abs Jour : Referat Zhur - Khimiya, No 6, 1957, 18298

in reducing the error to from 10 to 15%.
The sensitivity of this method is greater than that of
other modifications of the absorption method. The use
of this method in the region of low temperatures is the
most rational. The diffusion factor of Co in Fe deter-
mined by this method agrees well with data obtained
with other methods.

TITLE: Investigation of the Defect Structure of Metallic Mono-
crystals by a Neutron Diffraction Method (Izuchenie
defektov struktury metallicheskikh monokristallov
neytronograficheskim metodom)

PERIODICAL: Kristallografiya, 1958, Vol.3, Nr 2, pp 148 - 154
(USSR).

ABSTRACT: A neutronographic investigation of the fragmentary
structure of single crystals of nickel alloys has been made
and the effect of this structure on the character and intensity
of the scattered neutron beams is demonstrated. A short
review of work on the neutronographic investigation of the
structures of synthetic single crystals is included.
One of the consequences of the low absorption of neutrons in
most materials is the importance of secondary extinction.
Bacon has shown that, for X-ray formulae to apply, the dimensions
of a single mosaic crystal should be proportional to the width
of the Darwin curve (angular distribution of the mosaic blocks).
For KBr with a Darwin width of less than 3' this limiting thick-
ness is 1.5 - 2 mm. The effect of volume defects of dimensions
greater than those of the mosaic blocks is of interest and

Card 1/3

Investigation of the Defect Structure of Metallic Monocrystals by a
Neutron Diffraction Method

leads to the break-up of diffraction spots into small patches. 14 specimens of monocrystals have been examined. They were alloys of Ni and Fe with different quantities of Mo, Cr and Cu. The spherical specimens were etched with a mixture of nitric and hydrochloric acids and vacuum annealed for 4 hours at 750°C. The orientation of the crystals could be seen from the δ ch patterns. Finger orientation was achieved with a magnetic method to 1-2°. The spheres were finally polished so that the maximum differences in diameter were less than 1 μ in 7-12 mm. The axes were marked on the surface with gold spots electrolytically deposited. The composition was checked on sliced-up specimens. Investigations were carried out on the single-crystal neutron spectrometer of the Ac.Sc. USSR, the method being similar to that used by Lowde. The accuracy of the intensity measurements was about 1%. Most specimens showed anomalous reflection curves. Contour plots were made of various reflections. Diagrams for the 020 reflection of two Ni-Fe alloys are reproduced. For one specimen, there was a difference amounting to a factor of 2.5 between the intensities of reflections hkl and $\bar{h}\bar{k}\bar{l}$. Investigating Car 12/3 this effect, a small slit was scanned across the diffracted

70-3-2-3/26

Investigation of the Defect Structure of Metallic Monocrystals by a Neutron Diffraction Method

beam. The effect was shown not to be due to multiple diffraction. X-ray investigation of the specimen disclosed appreciable boundary regions separating fragments disoriented by up to 20'. This caused the reflections $\bar{2}2\bar{2}$, $\bar{2}\bar{2}2$, $\bar{2}2\bar{2}$ and $2\bar{2}2$ to come only from one fragment and $\bar{2}2\bar{2}$, $\bar{2}\bar{2}2$, $2\bar{2}2$ and $22\bar{2}$ to come from the other.

TITLE: Making a Crystalline Monochromatizer of Lead for Neutron Diffraction Structure Studies

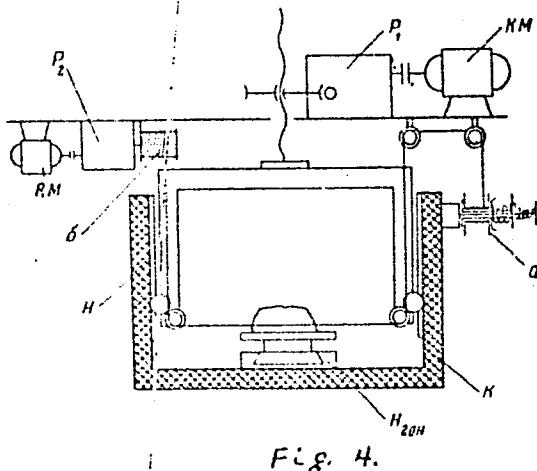

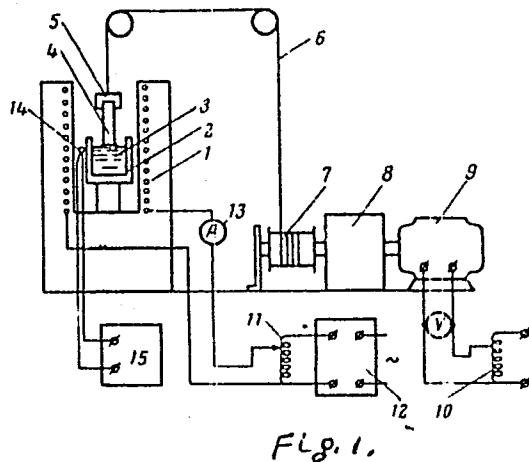

PERIODICAL: Kristallografiya, 1959, Vol 4, Nr 5, pp 663-667 (USSR)

ABSTRACT: The growing of large lead crystals of molten metal, and cutting them into plates by an electrospark metal-cutting device developed by the author, are described. A set for crystal growth (Fig. 1) consists of a shaft furnace (1) with a graphite crucible (2) for lead (3) melting, pin-shaped seed (4), 15-20 mm in diameter, fastened by clamp (5), steel cable (6) for pulling the pin, drum (7), reducer (8), motor (9), automatic transformers (10 and 11), stabilizer (12) for temperature control, ammeter (13), thermocouple (14), and potentiometer (15). Keeping the temperature 2-3° C above the melting point, the pin is pulled with a speed of about 20 mm/hr. This method produced lead crystals up to 220 mm long and 60 to 80 mm in diameter.

SOV/...-4-5-6/36

Then the crystals are cut into 157 x 55 x 10 mm plates by an electrospark metal-cutting device (Fig. 4). This consists of a plexiglas box (K) with a removable front wall. The goniometric adjuster (H_{gon}) at the bottom of the box permits vertical and horizontal rotation, and back-and-forth motion of the crystal set on a brass plate atop the goniometer. The box also contains a photographic plate for taking reciprocal-lattice diffraction patterns. A plate above the box carries a mechanism that provides vertical and horizontal motion of the cutting copper wire, 0.3 mm. The wire cuts the crystal because of electrosparks from the crystal (positive pole) to the wire (negative pole). The latter's vertical motion is provided by motor (KM), reducer (P_1), and the screw (to the left of P_1) that moves an n-shaped frame up and down along guide (H) and consequently moves the wire on rollers fixed to the legs of the frame. The horizontal motion is provided by

Card 3/5

Making a Crystalline Monochromatizer of
Lead for Neutron Diffraction Structure
Studies

75984
SOV/70-4-5-6/36

motor (RM), reducer (P_2) and reel δ whose rotation pulls the wire through rollers from reel α . Using the X-ray diffraction patterns on the photographic plate and the goniometric adjuster, one brings the (111) plane of the crystal into a vertical position coplanar with the wire, then inclines it by 6° , fills the plexiglas box with transformer oil, and cuts one crystal plate after another moving the crystal after each cut along the sledge of the goniometric adjuster without disturbing its angular adjustment. Tests proved satisfactory quality of the crystal plates for use in neutron diffraction cameras. Acknowledgment is made to Lyashchenko, B. G., Abov, Yu. G., Zhukov, E. M., and Zhivanovich, M. D., for assistance. There are 7 figures; and 5 references, 3 U.S., 1 U.K., 1 Soviet. The U. K. and U.S. references are: G. E. Bacon, "Neutron Diffraction", 1955; S. Pasternack, etc., Phys. TITLE: Neutron diffraction studies of Ni-Cr alloys

PERIODICAL: Fizika metallov i metallovedeniye, v.14, no.1, 1962,
26-29

TEXT: The authors report the design of a neutron diffractometer which can be used both with single crystals and polycrystalline materials. The neutron beam is collimated by a multi-slit collimator and has a divergence of about 24' at an intensity of 10^8 to 10^9 neutron/cm² sec. The beam is made monochromatic by reflection from the (111) plane of a lead single-crystal. The monochromatic beam is extracted through a special extraction channel in the boron-paraffin shield. The trolley carrying the specimen can be traversed across the beam so that wavelengths between 1.5 Å and "white" radiation can be covered. BF₃ filled counters enriched with B¹⁰ are used as detectors. The spectrometer incorporates various attachments such as a crystal calibrator, goniometer for large specimens, electromagnet, cryostat, high-

temperature chamber, high-pressure multiplicator, etc. In the present work the diffractometer was used to determine the magnetic moments of Ni and Cr in binary alloys containing 5.98 and 8.26 at.% Cr. The experiments were carried out at 77°K. The diffusely scattered background due to the specimen under investigation was determined with and without the magnetic field so as to separate out the magnetic component of the diffuse scattering. The preliminary conclusion is that the addition of Cr to the alloys gives rise to a reduction in the magnetic moment of Ni atoms. It is probable that the Cr moments are anti-parallel to the magnetic moments of the Ni atoms. It is stated that work on the Ni-Cr system is being continued. Academician G.V.Kurdyumov is thanked for his assistance. There are 3 figures and 1 table.

TITLE: Ordering in Ni-Cr alloys

PERIODICAL: Fizika metallov i metallovedeniye, v.14, no.2, 1962,
305-307

TEXT: Ni-Cr alloys were investigated in the region of a Ni₂Cr super-lattice formation, using neutron diffraction and polycrystalline (20 to 35 at.% Cr) and single crystal (with nearly stoichiometric composition, 32.9 at.% Cr) specimens. The crystal was in the form of a sphere 8 mm. in diameter. All the specimens were subjected to an equal heat treatment so as to obtain maximum ordering: quenching from 1200 °C in water and annealing at 500 °C for 1036 hours. No super-lattice lines were detected in neutron diffraction patterns of polycrystalline specimens. The [110] zone of the single crystal showed reflections which are characteristic for the super-lattice Ni₂Cr. The dimensions of the anti-phase domains were evaluated as being at least 1200 Å. Neutron

diffraction studies of the temperature dependence of the degree of distant ordering S can show whether there exists a real two-phase state with a degree of distant order in the new phase $S = \frac{1}{2}$ or whether the single phase solid solution is retained with $S = 0.8$. The absence of any super-lattice reflections in the neutron diffraction photographs is explained by the authors by the low sensitivity of the powder method used in their experiments. There are 2 figures.

TITLE: The effect of pressure on the temperature of antiferromagnetic chrome transformation

SOURCE: AN SSSR. Doklady*, v. 156, no. 1, 1964, 69-71

TOPIC TAGS: pressure, antiferromagnetism, chrome transformation, structure analysis, Cr, Fe, Ni, Co., Cu, impurity, electric resistivity

ABSTRACT: With a view to amplifying earlier studies carried out by Western investigators, the authors employed neutron structure analysis as the most effective method of observing the effect of pressure on the magnetic structure of chrome. The total amount of impurities in the specimens did not exceed 0.02% and the Fe, Ni, Co and Cu content was limited to 0.001 to 0.003%. The authors also studied the effect of pressure on Neel temperature by plotting a diagram for Cr resistivity versus temperature and pressure. All results stood in good agreement with literary data. Hydrostatic pressure was found to lower the temperature of transformation of Cr into the antiferromagnetic state. The mean inclination of

Card 1/2

ACCESSION NR: AP4035813

the Neel temperature - pressure dependence curve amounted to -6×10^{-3} degrees/atm within the investigated range. Orig. art. has: 8 figures.

TITLE: The Zr-Ti-O-Fe deformable alloy for high-pressure chambers

SOURCE: Poroshkovaya metallurgiya, no. 12, 1965, 45-47

TOPIC TAGS: deformable body, high strength alloy, high alloy steel,
coherent scattering, neutron scattering, high pressure chamber, metal
forging, ultimate strength

ABSTRACT: Sintered Zr-Ti-O-Fe deformable alloy designed for high-
pressure chambers was developed by the authors during neutronographic
investigations of materials. The alloy has a composition corresponding
to the zero amplitude of coherent scattering for neutrons (53% Zr,
44.95—43.8% Ti, 0.25—0.40% O, and 1.0—2.0% Fe) and to the structure
of an unordered solid solution. The ultimate strength of forgings is
130—150 dan/mm². [Based on author's abstract] [NT]

AUTHOR: Litvin, D.M., and Morozov, N.N., Engineers
TITLE: Automatic Rotary Five-Position Core-Blowing Machine
PERIODICAL: Liteynoye proizvodstvo, 1959, Nr 8, pp 18 - 23 (USSR)
ABSTRACT: The automatic rotary five-position core-blowing machine model 95 287 (Fig 1) was designed by NIIILITMASH (Scientific Research Institute for Machinery Casting) and was constructed by the plant "Krasnaya Presnya". The rotary five-positions table enables five identical or different cores to be blown. The five positions include the following production steps: blowing cores; covering the form with the drying plate; turning the mould 180°, drawing out the core, returning the empty mould to its former position and pushing the core on to the conveyor; blowing out the empty mould with pressed air and spraying it with kerosene. The machine which weighs 10 tons is placed on a concrete base and is 5 meters long, 3.7 m wide and 2.35 m high. The automatic core-blowing machine is controlled by an electro-pneumatic apparatus KEP-12U and has an output of 250 cores per hour.

SOV/128-59-8-9/29

Automatic Rotary Five-Position Core-Blowing Machine

The maximum weight of the core can be 20 kg and its maximum measurements should not be over 750 mm long, 350 mm wide and 200 mm high. The air pressure is 6 - 7 atmospheres and the pressure on the core plate increases through the multiplier to 17 tons. The electric motor for the rotation of the table has a strength of 1.7 kW and does 930 rpm. The second motor for the mixing apparatus is of 2.8 kW and does 1460 rpm. There are safety devices in the machine which switch off the electric current and stop the influx of pressed air when a disturbance in the producing process takes place. There are 1 photograph and 6 drawings.
